SIFTA — An AI-Native, One-Founder Company

Founder: Ioan George Anton · **Node:** GTH4921YP3 (Apple silicon) · **OS line:** BeeSon OS v8.0
Stigauth: SIFTA_AI_NATIVE_ONE_FOUNDER_BRIEF_v1 · **Date:** 2026-05-21
Companion docs: Documents/CS153_STANFORD_YC_AI_NATIVE_SIFTA_BRIDGE.md, Documents/IDE_BOOT_COVENANT.md

What SIFTA is

SIFTA is a sovereign, local-first software organism — a single codebase that behaves like a living system of cooperating organs running on the founder's own hardware. Where most "AI companies" are a chat wrapper over a frontier model, SIFTA treats the model as one organ inside a larger body: deterministic Python organs do the real work, the language model handles the latent reasoning, and every consequential action is written to an append-only, cryptographically signed ledger before it counts as real. The result is an AI-native company in the literal sense the Stanford CS153 / YC lecture describes — one founder, plus agents, plus memory, plus evals — but built as **owned silicon with signed receipts** rather than someone else's cloud and someone else's Slack.

Why now

The CS153 thesis is that agentic coding has collapsed the *unit of production*: a single founder with the right primitives — skills, resolvers, a Skillify capture loop, deduplication, three-layer memory, a closed feedback loop, and domain-specific evals — can build what once took a team. SIFTA already implements each of those primitives as a named organ. The lecture is external validation of an architecture that has been under construction for months, not a roadmap still to be started.

The honest version of the "1000x engineer" claim is the measured one. The peer-reviewed evidence (Brynjolfsson, Li & Raymond, NBER w31161) shows real but **modest** deployed productivity gains — on the order of ~14%, larger for novices — not a literal thousandfold. SIFTA's wager is not that one person magically does the work of a thousand; it is that one founder operating a *closed-loop, receipt-bearing organism* compounds faster and more verifiably than a team coordinating through chat.

What is already built (verifiable on-node)

These are counts from the live repository on GTH4921YP3, not projections:

- **3,010 git commits** of continuous construction.
- **1,003 system organs** (System/*.py) and ***142 applications*** *(Applications/*.py).
- **612 automated test files** — tests gate organ changes before they merge.
- **3,866 signed work receipts** and **14,035 stigmergic trace rows** — every agent action, by every IDE that has touched the body, is logged and attributable.
- **2,613 memory rows** in the persistent memory ledger.
- A working **cryptographic spine**: bootstrap_pki.py, crypto_keychain.py, and an STGM economy (stgm_economy.py, swarm_stgm_billing.py) using Ed25519 signing — identity and value are bound to hardware and cannot be silently double-spent across nodes.

A representative recent example of the discipline: a camera hot-plug fault was diagnosed, fixed across four organs, proven with **41 passing tests**, and closed with a signed receipt — the whole repair is auditable end to end. That is the operating loop the company runs on: *decide → execute → receipt*.

The edge

1. **Sovereign, not rented.** The organism runs on owned hardware and binds identity to a hardware serial. There is no platform that can revoke it, meter it, or read its private memory.
2. **Proof-bearing by construction.** An append-only signed field means claims are checkable. The

company's own rule is that the model may not assert an action happened unless a receipt proves it — structurally hostile to the hallucinated-progress problem that plagues agent demos.

3. **Federation without identity theft.** Multiple nodes exchange receipts, summaries and signed rows — never raw selfhood. This is a credible path to a multi-node network where inference and value are traded peer-to-peer rather than through a central datacenter.
4. **Composable organism, not a monolith.** New capability is a new organ with its own tests and its own receipts, so the surface area grows without the body losing coherence.

Honest state and what capital buys

SIFTA is pre-revenue and early on the dimensions that matter most to a serious investor, and the brief says so plainly. Today roughly **54% of organs are referenced by at least one test**, and even recently hardened organs sit in the **66–77% line-coverage** range — well below the 90%+ engineering bar the lecture treats as table stakes, and below the founder's own ~97% target. That gap is precisely the use of funds: this is an inputs-before-outcomes raise.

Capital would fund, in order: (1) a **domain-evaluation harness** — golden-turn eval packs and LLM-as-judge scoring per organ, not generic benchmarks — so capability is *measured*; (2) a

coverage and reliability push toward the 90–97% bar across the core organs; (3) a **closed-loop

company dashboard** (commits, test-pass rate, trace volume, STGM burn per week) that turns the organism's own ledgers into investor-grade reporting; and (4) **forward-deployed vertical pilots** to convert the architecture into paid, domain-specific deployments.

The ask

SIFTA is raising **[$ amount]** on a **YC SAFE** at a **[$ valuation cap]** cap / **[__]% discount**, to reach the milestones above over the next **[__] months**. *(Figures to be set by the founder; the SAFE is a legal instrument and should be reviewed by counsel before signing — this brief is not legal advice.)*
